Re: University Station – Preliminary Traffic Impact Assessment

Date: October 2, 2012

Tetra Tech and Vanasse & Associates, Inc. (Tt/VAI) have completed a preliminary assessment of the traffic impacts associated with the refined development program for the University Station mixed-use, transit oriented development to be located off University Avenue in Westwood, Massachusetts (hereafter referred to as the "Project"). This assessment has been prepared in advance of a formal Traffic Impact and Access Study (TIAS) and focused on the following specific areas as they relate to the Project: i) trip-generation calculations and methodology; ii) trip distribution patterns; and iii) evaluation of the planned improvements that are to be completed along University Avenue, at the University Avenue/Blue Hill Drive interchange, and at the University Avenue/Canton Street/Dedham Street intersection to support the build-out of the Project.

The information that forms the basis of this preliminary assessment has been reviewed and conceptually approved by MassDOT with specific regard to the methodology used to establish the traffic characteristics of the Project and the anticipated trip distribution pattern, and is currently being evaluated with regard to the assessment of the planned transportation infrastructure improvements that are to be completed along University Avenue and at the University Avenue/Blue Hill Drive interchange and the University Avenue/Canton Street/Dedham Street intersection. The formal TIAS will build upon the analyses presented herein and will expand the scope of the study to include additional roadways and intersections outside of the University Avenue corridor, consistent with the prior traffic analyses that were conducted for the former Westwood Station development.

Based on a review of the findings of this preliminary assessment, we have concluded that the Project, as presently contemplated, can be accommodated with defined improvements at the University Avenue/Blue Hill Drive interchange and at the University Avenue/Canton Street/Dedham Street intersection accompanied by the

reconstruction of University Avenue. The following summarizes our preliminary assessment of the Project and the infrastructure improvements along the University Avenue corridor.

Project Description

As presently contemplated, the reconstituted Project will entail the phased development of approximately 2 million square feet (sf) of mixed-use commercial and residential space to be located on approximately 130 acres of primarily vacant, partially cleared land located in the underutilized University Avenue Industrial Park and proximate to the I-93/I-95 interchange and within walking distance of the Massachusetts Bay Transportation Authority (MBTA) Route 128 Station on the Providence/Stoughton Commuter Rail Line in Westwood. The current development program (2 million \pm sf) represents a significant reduction (approximately 56 percent) from the previously proposed build-out of the Project (4.5 million \pm sf of mixed use development formerly known as Westwood Station) and the associated impacts on the transportation system. As proposed, the reconstituted Project¹ is expected to consist of the following components:

- 140,000 sf supermarket
- 610,000 sf of retail/restaurant space
- 325,000 sf of office space
- 160 room hotel
- 750 residential units to be generally comprised of:
 - 100 units of senior housing
 - 450 apartments
 - 200 condominium/townhouse units

Access to the Project will be provided by way of an interconnected network of roadways, sidewalks and bicycle facilities that will link the uses within the Project site to University Avenue and the Route 128 MBTA station. University Avenue will be reconstructed in conjunction with the Project following a *Complete Streets* design approach. Associated improvements are being advanced by MassDOT at both Blue Hill Drive/Greenlodge Street and Canton Street that will support the Project and the planned reconstruction of University Avenue. The previously proposed Westwood Station Boulevard has been eliminated from the Project given that the improved University Avenue will afford sufficient capacity to accommodate the current development proposal in a safe and efficient manner, thereby: i) reducing the land

¹The Proponent reserves the opportunity to reallocate uses provided the overall total impacts are not increased.

alteration and wetland impacts that were associated with the construction of Westwood Station Boulevard; and ii) reducing the potential traffic impacts on the upper portion of Canton Street.

Project Trip Generation

The traffic characteristics of the Project were developed using information obtained from *Trip Generation* published by the Institute of Transportation Engineers $(ITE)^2$ for land uses similar to those to be contained within the Project. ITE Land Use Codes (LUCs) 230, *Residential Condominium/Townhouse*; 220, *Apartment*; 252, *Senior Housing – Attached*; 310, *Hotel*; 710, *General Office Building*; 820, *Shopping Center*; and 850 *Supermarket*; were used to establish the base (unadjusted) traffic characteristics of the Project. In order to account for the interaction between the retail uses to be located within the Project site (i.e., retail, restaurant and supermarket uses), the traffic characteristics of the combined retail/restaurant/supermarket space (750,000 sf) were determined using LUC 820, *Shopping Center*, and then proportionately reduced to reflect the 610,000 sf of retail/restaurant space, thereby eliminating trips associated with the supermarket use from the calculation as the traffic characteristics of the supermarket were developed separately.

Factors influencing the total generated trips within a mixed-use development similar to the Project include: i) travel mode selection (automobile, transit, pedestrian or bicycle); ii) internal trips (trips made between uses within the Project); iii) pass-by trips (motorists travelling on the roadway network immediately adjacent to the Project site for other purposes that will also patronize the Project); and iv) diverted linked trips (similar to pass-by trips except that the motorist will divert or alter their original travel path to patronize the Project site). The following details the procedures used to apply these adjustments to the base traffic volume projections for the Project. The following details the procedures used to apply these adjustments to the base traffic volume projections for the Project. The detailed trip generation calculations are provided in Attachment A.

²*Trip Generation*, 8th Edition; Institute of Transportation Engineers; Washington, DC; 2008.

Transit Mode Share. The transit mode share for residential trips was based on a study conducted for the former Westwood Station development by the Central Transportation Planning Staff (CTPS) of the Boston Metropolitan Planning Organization (Memorandum to Efi Pagitsas from Thomas J. Humphrey regarding *Analysis of Projected Commuter Rail Shares of Trips Generated by Development at Route 128 Station*, March 15, 2006). This study is contained in Attachment B.

The CTPS memorandum described two residential developments located in the vicinity of commuter rail stations in eastern Massachusetts: Jefferson at Salem Station located off Bridge Street in Salem and Windsor Gardens located off Route 1A in Norwood. Surveys of the residents of these developments indicate transit ridership at the Norwood site at 18 percent during the morning peak-hour and 11 percent during the afternoon peak-hour, and at the Salem site at 46 percent during the morning peak-hour and 40 percent during the afternoon peak-hour. In their analysis, the CTPS suggested that the transit utilization rates documented for the Jefferson at Salem Station project (46 percent for the morning peak-hour and 40 percent for the afternoon peak-hour) be used for the Project as the commuter rail service to Salem Station is similar to that provided at the Route 128 Station.

A review of the Salem location indicates that the site lacks convenient highway access, access which is available to the Norwood site. In this respect (convenient highway access), the Project is more aligned with the Norwood site then to the Salem site; however, the frequency of train service at the Salem site (10 trains in the morning and 10 trains in the afternoon) is more analogous to the service available to the Project site (10 trains in the morning and 7 trains in the afternoon) than the Norwood site (5 trains in the morning and 5 trains in the afternoon). Accordingly, after a careful review of this information, the transit share for the Project was estimated by using the Norwood rates (18 percent in the morning and 11 percent in the afternoon) and then doubling the resulting value in order to account for the increased frequency of service that will be available to the Project site by way of the Route 128 Station (10 trains at Route 128 Station vs. 5 trains at Norwood Station). This results in a 36 percent transit share for the Project during the weekday morning peak-hour and a 22 percent transit share during the afternoon peak hour, far less than the 40 to 46 percent transit share suggested by CTPS for the residential component of the Project.

The transit mode share for office trips was also developed based on data provided by CTPS in its March 2006 memorandum. The CTPS memorandum provided an evaluation of 2000 Journey-to-Work data from the US Census which indicated that 10 percent of workers in Westwood are from Boston and 11 percent of work trips from Boston to Westwood are via transit. The CTPS memorandum also indicated that approximately one-half of all transit trips arriving at Route 128 Station in the morning are from Boston. Further, evaluation of the 2000 Journey-to-Work data indicates that approximately

2.1 percent of all workers in the vicinity of the Project site (Census Tract 412300, Block Group 1) travel to work by bus or another transit mode. Given that the office buildings proposed as a part of the Project are within walking distance of the Route 128 Station and that the Project will include specific amenities that will encourage use of public transportation resources (i.e., interconnected sidewalk and bicycle network and a Transportation Demand Management (TDM) program), a 3.0 percent transit share was assumed for weekday Project-related office trips.

Transit utilization by employees and patrons of the retail/restaurant component of the Project are anticipated to be similar to that expected for the office component. However, given: i) the variability of retail employee schedules; ii) the duration of employee shifts (often hourly blocks of time vs. an 8 hour day); and iii) the limited ability to incentivize retail/restaurant patrons to use transit; it is expected that such utilization will occur at a more diminished rate. Accordingly, the transit mode share for weekday Project-related retail/restaurant trips was assumed to be one-half of that assumed for the office component, or 1.5 percent.

A transit share was not applied to trips associated with the hotel component of the Project nor for Project-related trips during the Saturday midday peak-hour.

Internal Trips. Estimates of internal trips for the Project were developed based on the methodologies contained in the *Trip Generation Handbook*, 2^{nd} *Edition* published by the ITE.³ The internal capture trip rates are based on data collected at several mixed-use developments in Florida in the 1990s between 12:00 PM and 6:30 PM, and were applied only to auto trips. Based on this approach, the overall computed internal trip reductions for the Project would be approximately 11 percent for the weekday morning peak-hour, 7 percent for the afternoon peak-hour and 6 percent for the Saturday midday peak-hour.

Although this methodology results in reasonable overall internal trip reductions for the Project, closer inspection of the impact to the trip-generation for specific land uses indicates that total residential trips would be reduced by 40 percent during both the weekday morning and Saturday midday peak hours, a reduction that would be unrealistic. Accordingly, internal trips for the residential component of the Project were capped at 10 percent for the weekday morning and Saturday midday peak hours. With this adjustment, the overall computed internal trip reductions for the Project would be approximately 5 percent for the weekday morning peak-hour, 7 percent for the weekday afternoon peak-hour and 3 percent for the Saturday midday peak-hour. The supporting calculations for the ITE methodology for shared trips are provided in Attachment A.

³*Trip Generation Handbook*; Second Edition; Institute of Transportation Engineers; Washington, DC; June 2004.

Recently, new internal capture trip rates have been proposed as a result of National Cooperative Highway Research Program (NCHRP) Project 8-51 and are being evaluated by the ITE for promulgation as a part of the 3rd edition to the *Trip Generation Handbook*. NCHRP Project 8-51 included data collection to support internal capture rates for retail, office, residential, restaurant, hotel and cinema land uses for both the weekday morning and afternoon peak hours. Using the data contained in NCHRP Project 8-51 as summarized in the August 2010 ITE Journal article titled "Improved Estimation of Internal Trip Capture for Mixed-Use Development" and fully documented in NCHRP Report 864 Enhancing Internal Trip Capture Estimation for Mixed-Use Developments (Transportation Research Board, 2011), an internal trip rate of 16 percent was calculated for the Project for the weekday morning peak-hour and a 6 percent internal trip rate was calculated for the afternoon peak-hour. These rates are provided for comparison purposes only and serve to further validate the 5 to 7 percent internal capture trip rates that were used for the weekday peak hours for the Project.

Pass-By Trips. Pass-by trips are derived from the existing traffic stream on roadways adjacent to the Project site. With specific regard to the Project, pass-by trips would be derived from University Avenue. The No-Build traffic volume projections for University Avenue estimate 1,300 vehicles per hour during the weekday morning peak-hour, 1,000 vehicles per hour during the weekday afternoon peak-hour and at 200 vehicles per hour during the Saturday midday peak-hour. Based on these projections, the pass-by trip rate for the Project was held at 10 percent, 5 percent and 2 percent for the weekday morning, weekday afternoon and Saturday midday peak hours, respectively, and were applied to the automobile trips associated with the retail/restaurant and supermarket components of the Project. This approach results in a reasonable approximation of the traffic volume contribution from University Avenue that may be associated with the Project.

Diverted Linked Trips. Diverted linked trips are trips already on study area roadways that will divert to the Project site on their way to/from their primary destination. Consistent with the previously approved approach for estimating the contribution of pass-by and diverted linked trips for the Project, the combined pass-by/diverted linked trip percentage was limited to 20 percent. Therefore, diverted linked trips were estimated as 10 percent of the weekday morning peak-hour retail auto trips, 15 percent of the weekday afternoon peak-hour retail auto trips and 18 percent of the Saturday midday peak-hour retail auto trips. It is important to recall that diverted linked trips, although not new trips on the roadways from which they are diverted, do represent new trips on the roadways immediately proximate to the Project site.

Summary. Table 1 in Appendix A summarizes the weekday morning, weekday afternoon and Saturday midday peak-hour trip generation calculations for the Project and include total, auto, internal, external, pass-by, diverted linked and new trips for each of the proposed land uses. With the adjustments to account for transit share, pass-by, diverted linked and internal trips, the Project is expected to generate approximately 1,563 new vehicle trips during the weekday morning peak-hour (1,027 vehicles entering and 536 exiting), with 3,221 new vehicle trips expected during the weekday evening peak-hour (1,504 vehicles entering and 1,717 exiting) and 3,762 new vehicle trips expected during the Saturday midday peak-hour (1,971 entering and 1,792 exiting).

Trip Distribution

Regional distribution patterns were developed for the office, residential and retail components of the Project taking into account: i) Journey-to-Work data obtained from the 2000 Census; ii) the market area for the Project (i.e., a population based gravity model); iii) accessibility of the Project site to/from the local and regional roadway network; and iv) the location of competing opportunities within the Project market area, including other grocery shopping opportunities along the Route 24 corridor (i.e., BJ's Wholesale Club, Costco, etc.). The trip-distribution calculations for the individual components of the Project are included as Attachment C to this document. Figures depicting the trip distribution patterns for each land use and the associated weekday and Saturday peakhour trip assignments are also provided in Attachment C.

Traffic Operations Analysis

In order to assess the adequacy of the improved transportation infrastructure to accommodate the Project in a safe and efficient manner, traffic operations and vehicle queue analyses were performed at the University Avenue/Blue Hill Drive interchange and at the University Avenue/Canton Street/Dedham Street intersection under 2017 and 2022 Build conditions with the full build-out of the Project.

In brief, six levels of service are defined for each type of facility. They are given letter designations ranging from "A" to "F", with a level-of-service (LOS) "A" representing the best operating conditions and a LOS "F" representing congested or constrained operations. A LOS "E" is representative of a transportation facility that is operating at its design capacity with a LOS "D" generally defined as the limit of "acceptable" traffic operations. Since the level-of-service of a traffic facility is a function of the flows placed upon it, such a facility may operate at a wide range of levels of service depending on the time of day, day of week, or period of the year. The Synchro® intersection capacity

analysis software, which is based on the analysis methodologies and procedures presented in the 2000 Highway Capacity Manual (HCM), was used to complete the level-of-service and vehicle queue analyses for the study intersections.

The traffic volumes that form the basis of this preliminary analysis were developed using accepted transportation planning methodologies as follows and will be updated and refined in conjunction with the preparation of the subsequent TIAS that will accompany the NPC filing for the Project:

- 1. 2012 traffic count data was obtained and increased by a compounded annual traffic growth rate of 0.5 percent per year to represent 2017 and 2022 Baseline (No-Build) traffic volume conditions;
- Traffic volumes associated with the reoccupancy of 200,000± sf of currently vacant office space on Rosemont Drive and 27,000± sf of light industrial space on University Avenue south of Yale Street were added to the Baseline traffic volumes (2017 and 2022);
- 3. The Blue Hill Drive ramp improvements were assumed to be complete within the 2017 horizon year;
- 4. The Blue Hill Drive ramp improvements, the I-95 northbound off-ramp to Dedham Street and the Dedham Street corridor improvements were assumed to be complete within the 2022 horizon year; and
- 5. Traffic volumes for the full build-out of the Project were developed and added to the 2017 and 2022 Baseline traffic volume conditions.

Attachment D includes the 2017 and 2022 Build condition traffic volumes that form the basis of this assessment. The reassignment of Baseline traffic that will result from the completion of the Blue Hill Drive ramp project is reflected in the 2017 horizon year.

For the 2022 horizon year, preliminary estimates have been made that account for the redistribution of Baseline traffic which will occur upon completion of the I-95 northbound off-ramp to Dedham Street. Project-related traffic reassignments that will result from the completion of the I-95 northbound off-ramp to Dedham Street are also reflected in the 2022 horizon year analysis. Attachment D includes figures illustrating the anticipated reassignment of Project-generated traffic that is expected to occur as a result of these improvements under 2022 Build conditions.

In addition, the following improvements depicted on Figures 1 and 2 were assumed at the University Avenue/Blue Hill Drive interchange and the University Avenue/Canton Street/Dedham Street intersection under both the 2017 and 2022 horizon years:

University Avenue/Blue Hill Drive (Figure 1):

- Realignment of the I-95 southbound off-ramp and extending the ramp to intersect University Avenue;
- Installation of a raised median separating the I-95 southbound on and off-ramps and reconfiguring intersecting driveways to reflect the resulting one-way traffic flow;
- Terminating Blue Hill Drive West in a cul-de-sac configuration west of the Blue Hill ramps;
- Widening the Blue Hill Drive off-ramp approach to University Avenue to accommodate a left-turn lane, a through travel lane and a channelized right-turn lane;
- Widening the Greenlodge Street approach to University Avenue to accommodate a left-turn lane and a through/right-turn lane;
- Reconstructing the University Avenue northbound approach to provide two (2) left-turn lanes and a shared through/right-turn lane;
- Reconstructing the University Avenue southbound approach to provide a left-turn lane, two (2) through travel lanes and a shared through/right-turn lane; and
- Installation of a fully actuated traffic signal system.

University Avenue/Canton Street/Dedham Street (Figure 2):

- Widening the Dedham Street westbound approach to accommodate a left-turn lane, a through travel lane and a channelized right-turn lane;
- Widening the Canton Street eastbound approach to accommodate a left-turn lane, a through travel lane and a shared through/right-turn lane;
- Widening the University Avenue northbound approach to accommodate a left-turn lane, a through travel lane and a right-turn lane;
- Reconstructing the University Avenue southbound approach to provide two (2) left-turn lanes and a shared through/right-turn lane; and
- Installation of a fully actuated traffic signal system.

The results of the intersection capacity and vehicle queue analyses are summarized in Tables 1 and 2 for 2017 and 2022 Build conditions, respectively. As detailed therein, the intersections of University Avenue at Blue Hill Drive and University Avenue at Canton Street and Dedham Street are expected to operate at an overall level-of-service of

"D" or better during the peak periods under both 2017 and 2022 Build conditions with the full build-out of the Project and the completion of the improvements described above and depicted on Figures 1 and 2. A further review of vehicle queuing at both intersections indicates that the planned intersection improvements are appropriately designed to accommodate the projected vehicle queue lengths without hindering intersection/interchange operations or the operation of the State Highway System.

Summary

Tt/VAI have completed a preliminary assessment of the traffic impacts associated with the refined development program for the University Station mixed-use, transit oriented development to be located off University Avenue in Westwood, Massachusetts. This assessment has been prepared in advance of a formal TIAS and focused on the following specific areas as they relate to the Project: i) trip-generation calculations and methodology; ii) trip distribution patterns; and iii) evaluation of the planned improvements that are to be completed along University Avenue, at the University Avenue/Blue Hill Drive interchange, and at the University Avenue/ Canton Street/Dedham Street intersection to support the build-out of the Project.

The information that forms the basis of this preliminary assessment has been reviewed and conceptually approved by MassDOT with specific regard to the methodology used to establish the traffic characteristics of the Project and the anticipated trip distribution pattern, and is currently being evaluated with regard to the assessment of the planned transportation infrastructure improvements that are to be completed along University Avenue and at the University Avenue/Blue Hill Drive interchange and at the University Avenue/Canton Street/Dedham Street intersection.

Based on a review of the findings of this preliminary assessment, we have concluded that the Project, as presently contemplated, can be accommodated with defined improvements at the University Avenue/Blue Hill Drive interchange and at the University Avenue/Canton Street/Dedham Street intersection accompanied by the reconstruction of University Avenue.

The information that forms the basis of this preliminary assessment will be refined in conjunction with the preparation of the formal TIAS for the Project and will include additional roadways and intersections outside of the University Avenue corridor, consistent with the prior traffic analyses that were conducted for the former Westwood Station development.

MEMORANDUM

TO: Efi Pagitsas

March 15, 2006

FROM: Thomas J. Humphrey

RE: Analysis of Projected Commuter Rail Shares of Trips Generated by Development at Route 128 Station

Introduction and Summary

As requested, I have reviewed the consultant's estimates of the commuter rail shares of total trips generated by proposed development at Route 128 Station. These trips would be generated by four categories of development: residential, office, retail, and hotel. The estimated commuter rail share of residential-based trips for either phase of development are plausible. The absolute numbers estimated for hotel development are so small that they have little effect on the total results.

For the Phase I development, office-based trips also account for a small part of the total projected ridership. However, for the Phase I + II development, office-based trips account for the largest shares of weekday ridership, and they appear to be about four times as large as would be likely. Retail trips are the largest source of estimated trips in the Phase I development and the second-largest source in the Phase I + II development, but they also appear to be about four times as large as would be likely. A detailed analysis is presented below.

Details of Findings

Trips Generated by Residential Development

The commuter rail share of all peak-period trips generated by residential development at the Westwood site is estimated by the consultant at 29%. This is between the observed values of 40-46% for the development at Salem Station and 11% to 18% at Windsor Gardens. At present, Route 128 and Salem are each served by 10 inbound AM peak trains, but Windsor Gardens is served by only 5. In the PM peak, Route 128 is currently served by 7 outbound trains, compared with 10 to Salem and 5 to Windsor Gardens. These figures suggest that the share of residential trips captured at Route 128 could be closer to that at Salem than to that at Windsor Gardens. With a share of 46% in the AM peak, commuter rail would serve 65 trips rather than 41 with the Phase I development, and 156 rather than 99 with the Phase I + II development. With a share of 40% in the PM peak, commuter rail would serve 65 trips rather than 45 with the Phase I development, and 152 rather than 110 with the Phase I + II development.

Efi Pagitsas

Trips Generated by Hotel Development

The consultant's estimate of commuter rail share of all peak-period trips generated by hotel development at the Westwood site is 6%. This presumably includes hotel workers and guests. No comparable situations are cited in the analysis. However, the maximum estimates of hotel-based weekday commuter rail trips range from 9 with a 235-room hotel to 16 with a 450-room hotel. Since these are very small components of the total estimated commuter rail ridership, they need not be of great concern even if they are too high.

Trips Generated by Office Development

The consultant's estimate of commuter rail share of all peak-period trips generated by office development is 11.0%. In absolute terms, this is only 16-17 trips for the Phase I development, so as in the case of hotel development, any over-estimation need not be of great concern. However, for the Phase I + II development, the projected totals of 401 AM peak and 386 PM peak trips account for the largest components of the total estimated commuter rail ridership, at 69% and 52%. Therefore, they need to be examined more carefully.

The 2001 CTPS Reverse Commuting Study used an upper-bound estimate of 11% for the commuter rail share of work-trips to Westwood from homes anywhere in Boston. This depended on an underlying assumption of convenient access between commuter rail stations and work locations, which would be the case for a Route 128 development. However, only about 10% of all jobs in Westwood are held by Boston residents. If this were also true of a Route 128 development, with the Phase I + II office complex generating 3,643 AM peak trips and 3,502 PM peak trips, Boston residents would be expected to make 364 and 350 of these. At 11%, the commuter rail shares of these trips would be 40 and 39.

Commuter rail would be expected to capture much smaller shares of work trips to Route 128 from locations other than Boston. Many of these trips would be expected to originate at points that do not have convenient access to stations on the Attleboro/ Stoughton commuter rail line. The 2003 survey of passengers using the TMA shuttle from Route 128 Station found that origins of those transferring from outbound trains were about evenly divided between Boston residents and passengers who first traveled into Boston from suburbs to access the commuter rail line. A similar ratio would raise the Westwood development office-based ridership on outbound AM peak and inbound PM peak trains to 80 and 78.

The final component of commuter rail ridership to be considered would be that between Route 128 and stations further south. Counts taken in December 2000 found that the number of inbound AM peak alightings at Route 128 was 24% as large as the number of outbound AM peak alightings. With similar proportions, office-based Westwood ridership to and from points further south would be about 19 in each peakperiod, raising the grand totals to 99 and 97. These are 75% lower than the estimates in the consultant's analysis.

Efi Pagitsas

Trips Generated by Retail Development

Retail-based trips would include a combination of trips by retail-establishment employees and customers of those establishments. For most retail businesses, customer trips would be the larger of the two groups. The commuter rail share of retail-based trips could theoretically include some riders from each group. However, use of the commuter rail system for shopping trips in the past has been very low. The 1993 MBTA commuter rail survey found that only 1.1% of the weekday trips on the lines then in operation had shopping as the activity at either end of the trip. The 1998 Old Colony Lines survey found even smaller percentages of shopping trips. Customers of "big-box" stores, buying large quantities of merchandise at one time, or buying large items such as furniture, would be even less likely than other retail customers to travel by commuter rail. For these reasons, estimates of commuter rail trips generated by retail development at Route 128 should be based mainly on employee trips.

The amount of retail development was assumed to be the same for either the Phase I project or the Phase I + II project, so the number of retail trips estimated by the consultant for either project was the same. The consultant's estimate of trips generated by retail development did not include separate breakdowns of employee and customer trips. The estimated total number of weekday trips by all means was 1,030 in the AM peak and 3,750 in the PM peak. This large difference is presumably a result of the late opening times of many retail business. The commuter rail share was estimated at 6%, or 62 in the AM peak and 225 in the PM peak.

Since customer trips could be expected to make up the majority of total trips generated by retail development, an upper-bound estimate of employee trips would be provided by assuming that they would equal half of all trips. This would be 515 in the AM peak and 1,875 in the PM peak. If it is assumed that retail employees of the development would be as likely as office employees to live in Boston and to use commuter rail, then applying the same factors used in the analysis above, 10% would live in Boston and 11% of these would travel by commuter rail. This would make 6 trips in the AM peak and 21 in the PM peak. Applying the same add-ons used for suburban trips via Boston and trips from points south of Route 128 would raise the total commuter rail trips to 14 in the AM peak and 51 in the PM peak. These are only 23% as large as the consultant's estimates.

Residential Transit Share

2000 Census Data - Residential Development

9.74% Live in Westwood and Commute by Train/Bus to Work

- 10.28% Live in Westwood in Westwood Station area and Commute by Train/Bus to Work
- 28.43% of Residents in vicinity of Westwood Station work in Boston
- 36.24% of Residents in vicinity of Westwood Station who work in Boston take the T to work
- 0.00% of Residents in vicnity of Westwood Station who work outside of Boston take the T to work

Memorandum Re Analysis of Projected Commuter Trail Shares of Trips Generated by Development at Route 128 Station (Efi Pagitsas, March 15, 2006)

- 40% to 46% Salem Station which is served by 10 inbound trains in the AM and 10 outbound trains in the PM (266 units) 11% to 18% Windsor Gardens (Norwood) which is served by 5 inbound trains in the AM and 5 outbound trains in the PM (914 units) Westwood Station is served by 10 inbound trains in AM and 7 outbound trains in the PM
 - Conclusion closer to Salem

Development of Transit Share for Westwood Station (Oak Square Resources, LLC, March 26, 2006)

- 33% Residential Transit Share
 - Based on:
 - AM PM
 - 46% 40% Salem Station
- 18% 11% Windson Gardens Norwood Average 32%

FEIR Westwood Station

46% Residential Transit Share

Tetra Tech Rizzo Interim Phase I 36% AM Residential Transit Share Double Norwood AM Transit Share - WS has double the service and is similarly located to hwy system

22% PM Residential Transit Share

Office Transit Share

2000 Census Data - Office Development

- 1.78% total transit use for commute TO Westwood
- 2.06% total transit use for commute TO Westwood station area
- 8.94% of Workers in vicinity of Westwood Station come from Boston
- 91.06% of Workers in vicinty of Westwood Station come from outside of Boston 13.20% of Workers in the vicinity of Westwood Station who come from Boston take the T to work
- 0.97% of Workders in the vicinity of Westwood Station who live outside of Boston take the T to work

Memorandum Re Analysis of Projected Commuter Trail Shares of Trips Generated by Development at Route 128 Station (Efi Pagitsas, March 15, 2006) 2.7% total transit for commute TO Westwood Station

Based on CTPS 2001 Reverse Commuting Study and 2000 Census data

10% of workers in Westwood are Boston residents

- 11% of work trips to Westwood from Boston use Transit
- 0.5 transit trips arriving in AM at Westwood are from Boston

Development of Transit Share for Westwood Station (Oak Square Resources, LLC, March 26, 2006)

3% Transit Share for Office Trips

Retail Transit Share

2000 Census Data

Memorandum Re Analysis of Projected Commuter Trail Shares of Trips Generated by Development at Route 128 Station (Efi Pagitsas, March 15, 2006) 1.4% Transit Share for Retail Trips

- Based on:
 - Employee Trips Only
 - 50% of trips would be generated by employees
 - 0.5 transit trips arriving in AM at Westwood are from Boston
 - 11% of work trips to Westwood from Boston use Transit
 - 10% of workers in Westwood are Boston residents
 - 0.5 transit trips arriving in AM at Westwood are from Boston

Development of Transit Share for Westwood Station (Oak Square Resources, LLC, March 26, 2006)

3% Transit Share for Retail Trips Based on:

Transit Share for Office Trips can be used for retail employees

FEIR Westwood Station

1.5% Transit Share for Retail Trips

Tetra Tech Rizzo Interim Phase I 1.5% Retail Transit Share

50% employee is high, but 1.5% seems reasonable
